COMP61511 (Fall 2019)
Software Engineering Concepts In Practice
Week 3
Bijan Parsia & Christos Kotselidis
<bijan.parsia, christos.kotselidis@manchester.ac.uk>
(bug reports welcome!)
Reflecting On Personal Qualities
3 Of 5

- We're at **Week 3**!
  - 3/5s done after today!
  - **Where** are you?
    - And where are you **going**?
    - What are the **next steps**?
- This is a good time to **reflect**
Reflection

*Reflection* is the process of examining one's own thoughts, beliefs, experiences, concepts, etc. in order to gain self-knowledge and insight.

- Reflection doesn't need to be nasty
  - You aren't looking for flaws
  - You are trying to understand yourself
  - This includes good things!
Reflection Example 1

- For CW2 some people handed in
  - Some people still had structural issues
    - E.g., didn't upload a zipped directory
Reflection Example 1 (Ctn)

- This is in spite
  - my mentioning it in lecture
  - it being described in the assignment
  - CW1 having the same requirement
    - And being graded and returned before CW2 was due!

What went wrong with their process? How to fix it?
Reflection Example 2

- Last Thurs afternoon
  - several people asserted that their code 100% should pass some simple tests
  - and that their code review found "no bugs"
- For some, we found they **could not pass any test**
  - In most scenarios
- What went wrong?
  - And **how do we fix it**
Reflection Example 3

- Look on the **discussion board**!
  - A lot of my replies are along the lines:
    - "On the one hand, you have what \textit{wc} does. On the other, you have a idea of how to do it differently. Which do you think should win?"
  - And that was **enough**!
    - How to get that **without** an **external prompt**?
Reflection Example 4

- People asked:
  - I fixed my miniwc.py will you retest it to check that it's right
  - I want to know that my interpretation is right
  - I just want to confirm my understanding so I don't lose points

- Reflect!
  - Do we understand why people asked these?
  - What's the right response?
  - What's would be a problem with answering these directly?

Are points the point of the coursework?
Reflection Example 4

- Look on the **discussion board**!
  - A lot of people **got stuck**
    - How and why?
    - Did **you** get stuck?
    - Did you get **unstuck**?
      - How?
Stuck?
Metacognition

*Metacognition is thinking about thinking*

- **Reflection** is one example
- In general, an important skill
  - For example, when you are **stuck**
    - it helps to check whether you are in a **rut**
    - that is, just **trying the same thing over and over**
  - Being aware that you got stuck can help you get unstuck!
A cognitive bias is a systematic departure from rationality.

- We all have them, and lots of them:
Cognitive Biases

Cognitive Bias Cheat Sheet
Because thinking is hard

1 Too Much Info
So only notice...
- Changes
- Bizarreness
- Repetition
- Confirmation

2 Not Enough Meaning
So fill in gaps with...
- Patterns
- Generalities
- Benefit of Doubt
- Easier Problems
- Our current mindset
3 NOT ENOUGH TIME

SO ASSUME...
- WE'RE RIGHT
- WE CAN DO THIS
- NEAREST THING IS BEST
- FINISH WHAT'S STARTED
- KEEP OPTIONS OPEN
- EASIER IS BETTER

4 NOT ENOUGH MEMORY

SO SAVE SPACE BY...
- EDITING MEMORIES DOWN
- GENERALIZING
- KEEPING AN EXAMPLE
- USING EXTERNAL MEMORY

BY @BUSTER
HTTP://BIT.LY/THINKING-IS-HARD
Self-Efficacy

Perceived self-efficacy is defined as people's beliefs about their capabilities to produce designated levels of performance that exercise influence over events that affect their lives.

- Too much self-efficacy
  - is overconfidence
- Too little self-efficacy
  - leads to underachievement
Two Key Biases

- **Bias-Blind Spot**
  - "The tendency to see oneself as less biased than other people, or to be able to identify more cognitive biases in others than in oneself."

- **Dunning-Krugar Effect**
  - "The tendency for unskilled individuals to overestimate their own ability and the tendency for experts to underestimate their own ability."

*Be very careful here!*
Goldilocks Self-Efficacy

- Both **too much** and **too little** are bad!
  - Too much == **bored**
  - Too little == **daunted** and uninterested

_Aim for the sweet spot!_
Goldilocks Science!

Awesomest paper title: "Self-efficacy and interest: Experimental studies of optimal incompetence"
Trajectory!

- Trajectory over current level
  - Current level is static
  - It informs trajectory
    - But doesn't determine it
- Reflection!
  - Are you learning quickly or slowly
  - Are you learning how to learn
A student who has mastered the [Core Body of Knowledge (CBOK)] will be able to develop a modest-sized software system of a few thousand lines of code from scratch, be able to modify a pre-existing large-scale software system exceeding 1,000,000 lines of code, and be able to integrate third-party components that are themselves thousands of lines of code. Development and modification include analysis, design, and verification, and should yield high-quality artefacts, including the final software product.

A Student Will...

- be able to develop
  - a **modest-sized** software system
    - of a **few thousand lines of code from scratch**,  
  - be able to **modify a...large-scale software system**
    - exceeding **1,000,000** lines of code, 
    - and be able to **integrate (1000s LOC) third-party components** 
- Development and modification include
  - analysis, design, and verification, and 
  - should **yield high-quality artefacts**,  
  - **including** the final software product.
WC?

- Where does `wc.py` get us?
  - For a **proper clone**
    - ≈ hundreds of LOC
    - OTOH, maybe under 100! `wc` golf?
  - **With extensions**
    - maybe 1000s?
  - Not counting **infrastructure**
    - Tests, etc.
- Does 100s predict 1000s?
  - Good question!
Look Around!

- **Modest size** software systems?
  - What do they **look like**?
  - What do they **do**?
  - Collect some **examples**!
- Remember **reverse engineering**
  - **Port** from a different language!
  - **Rewrite** from scratch
- Create something new!
Intellectual Property

© copyright
all rights reserved
Who Owns Your Code?

- You *wrote* some code!
  - All week!
  - Both systems and tests!
- A key question:
  - Who *owns* that code?
    - Or different bits of it?
  - What *kind* of ownership?
Intellectual Property (IP)

*Intellectual property* is any articulable, tangible production of a mind whose physical realisations are restricted by law (e.g., in distribution)

- We don't control what other people think!
- We can control what they *do* with certain thoughts.
# Kinds Of Intellectual Property

<table>
<thead>
<tr>
<th>Name</th>
<th>Establishment</th>
<th>Enforcement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Copyright</td>
<td>Automatic, immediate</td>
<td>Civil &amp; Crim</td>
</tr>
<tr>
<td>Patent</td>
<td>Application before exposure</td>
<td>Mostly civil</td>
</tr>
<tr>
<td>Trademark</td>
<td>Application and vigorous defense</td>
<td>Mostly civil</td>
</tr>
<tr>
<td>Trade Secret</td>
<td>Automatic or NDAs</td>
<td>Mostly civil</td>
</tr>
</tbody>
</table>
Copyright

Copyright is a licensable monopoly of tangible expression of an idea with respect to reproduction, derivation, display, distribution, and the like.

- Protects the expression not the idea
  - Though these blur at the limit
    - Some plagiarism is a copyright violation
- Typically automatically assigned at creation time
Patents

A **patent** is a licensable monopoly of the use or sale of a "non-obvious" **invention** (of a process, machine, design (sometimes), mechanism, procedure, etc.

- A patent is an **incentive to disclose**
  - Goal is to **add** to our **common** knowledge
- **Prior art** destroys a patent
A trade secret is an invention which is not disclosed

- Persists forever
  - Unless leaked
  - Or reinvented
- Typically protected by secrecy
  - Or specific contracts
    - "Non-Disclosure Agreements" (NDAs)
Who Owns Your Code?

- Copyright starts with the creator
  - I.e., you!
  - Cheap! (Even to register)
  - Unless you create it as work-for-hire
    - Or otherwise transfer it
- Patents belong to the patenter
  - Expensive(ish) to secure
- Trade secrets belong to the inventor
Are You Working For Hire?

- Not quite!

3.6. Student IP Licence to the University

3.6.1. Each Student grants to the University a licence to use the:

3.6.1.1. IP created by him or her in the course of his/her studies at the University and which they own; and

3.6.1.2. IP in any thesis or dissertation submitted to the University for the award of a degree.

3.6.2. In each case, the licence will take effect upon the creation of the relevant IP.

3.6.3. The licence:

3.6.3.1. is a continuing, non-exclusive, worldwide, irrevocable, royalty-free licence to use the IP in any format (whether existing or future);

3.6.3.2. will last for as long as the relevant IP remains in existence; and

3.6.3.3. is granted so that the University can (i) use such IP for its and its subsidiaries’ administrative, promotional, educational and teaching purposes; and (ii) do all such things in relation to such IP which would otherwise be an infringement of such IP.
3.6.4. As part of the licence, the University is also permitted to sub-license to others the rights granted to it by Students.

3.6.5. Any thesis or dissertation submitted to the University for the award of a degree may be placed by the University in its institutional repository in electronic or other format.
What To Keep In Mind (Now)

- Software engineers typically **produce** IP
  - Even if not protected, our **output** is "intellectual"
  - Various forms of IP drive
    - **product** value
    - **employee/entrepreneur** value
- Software engineers typically **use** IP
  - All sorts and in all ways
  - IP considerations a constraint on the design space
Some Internal Qualities
Software Quality Landscape

20.1. Characteristics of Software Quality

<table>
<thead>
<tr>
<th>External Qualities</th>
<th>Internal Qualities</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Functional</strong></td>
<td><strong>Non-Functional</strong></td>
</tr>
<tr>
<td>Correctness</td>
<td>Usability</td>
</tr>
<tr>

<td>Understandability</td>
</tr>
<tr>
<td>Portability</td>
<td></td>
</tr>
<tr>
<td>Reusability</td>
<td></td>
</tr>
<tr>
<td>Testability</td>
<td></td>
</tr>
</tbody>
</table>
Thus Far We Looked At...

- External
  - Functional
    - Correctness (the functional quality)
  - Non-functional (a bit)
    - Efficiency (the non-functional quality)
- Now, some internal
  - Testability
  - For Modification
    - Maintainability
Internal: For Modification

- **Maintainability**
  - ease to "change or add capabilities, improve performance, or correct defects"

- **Flexibility**
  - ease to modify for new situations ("internal" version of adaptability)

- **Portability**
  - ease to modify for new environments

- **Reusability**
  - ease to extract parts for use in other systems
Internal: For Comprehension

- **Readability**
  - ease of comprehending the **source code**
- **Understandability**
  - ease of comprehending the software **system**
    - from the **synoptic** ("bird's eye") view
    - to the **myopic** ("worm's eye") view

Readability is part of understandability. But you can have readable methods or functions and an impossible to grasp architecture.
A critical property!
  - Relative to a **target quality**
    - A system could be
      - highly testable for **correctness**
      - lowly testable for **efficiency**
  - Partly determined by test infrastructure
    - Having **great hooks** for tests pointless without **tests**

Practically speaking
  - Low testability blocks **knowing** qualities
  - Test-based evidence is essential
Problem Indicators

- **Code Smell**
  - "a surface indication that usually corresponds to a deeper problem" (Kent Beck via Martin Fowler)
  - Quick to spot (if you have experience)
  - Doesn't always correspond to a problem
  - The "WTF test"

- **Pain Points**
  - A part of the system that recurrently causes problems
Testability Smell

def get_file_list():
    # Get list of arguments from the command line, minus "wc.py"
    args_list = sys.argv[1:]
    ...

def get_max_width():
    max_val_list = []
    for rec in file_log:
        max_val_list.append(rec.get_max_value())
    return max(max_val_list)

Thanks to the brave student who volunteered their code!
def get_file_list(args):
    # Get list of arguments from the command line, minus "wc.py"
    args_list = args[1:]
    ...

so we can test by:

```python
>>> import wc
>>> wc.get_file_list(['wc.py', '-l', 'filename.txt'])
```

*Thanks to the brave student who volunteered their code!*
Testability Smell 2

What about:

```
#all the module's code
wc()
```

Thanks to the brave student who volunteered their code!
Testability Smell 2 FIXED

We want to import the module without running anything!

```python
# all the module's code
if __name__ == "__main__":
    wc()
```

Now, `import wc` doesn't `run wc()`

*Thanks to the brave student who volunteered their code!*
Refactoring

- Notice
  - None of these moves *changed functionality*
    - Or pretty much any external quality
  - But we *improved*
    - testability
    - maybe readability and maintainability
    - reusability!
- We *refactored* the code
Why Did These Things Happen?

- Haste
- Lack of understanding
  - Of the problem
  - Of the tools
    - E.g., Python
- Someone Else's Code
- Just an accident!
  - Seemed like a good idea at the time!
A Consequence

- Remember the Testable Function's tests

```python
>>> import wc
>>> wc.get_file_list(['wc.py', '-l', 'filename.txt'])
```

- What do tests look like for:

```python
def get_file_list():
    # Get list of arguments from the command line, minus ",
    args_list = sys.argv[1:]
...```
Test Consequences

- Maybe

```python
>>> import subprocess
>>> subprocess.check_output('python wc -l filename.txt')
```

- or

```python
>>> import sys, wc
>>> sys.argv = ['wc.py', '-l', 'filename.txt']
>>> wc.get_file_list()
```

Are these easy to maintain?
Technical Debt

- Our lack of testability is like a **debt**
  - We might have to **pay it off** in the future
    - By refactoring
  - If we **wait** it **incurs interest**
    - The **more tests** we write, the more tests we have to **change later**
    - Our current tests are
      - Hard to write
      - Hard to read
      - Maybe buggy!
- Debt breeds more debt!
Technical Debt
Technical Debt

*Technical debt* is "the obligations incurred by a software organization when it chooses an expedient design or construction approach that increases complexity and [cost] in the long term."

- Typically, **lower (internal) quality level**
- It may **buy an external quality effect**
  - More **functionality** (correctness)
  - More **efficiency**
Technical Debt

*Technical debt* is "the obligations incurred by a software organization when it chooses an expedient design or construction approach that increases complexity and [cost] in the long term."

- It may have **negative** external effects
- It may just buy **project** effects
  - E.g., developer effort
Debt Taxonomy

Type 1: Unintentional Debt (results of poor development practices)

Type 2: Intentional Debt

2.A: Short-term Debt (incurred for tactical reasons)
- 2.A.1: Identifiable significant shortcuts (similar to a car loan)
- 2.A.2: Identifiable tiny shortcuts (similar to credit card debt)

2.B: Long-term Debt (incurred for strategic reasons)

Non-Debt
- Feature backlog, deferred features, cut features, technological relevance, etc.
- (These aren’t debt, because they don’t require interest payments.)

Technical Debt Taxonomy
Intentional Vs Unintentional Debt

- **Unintentional** debt == accidental or incidental
  - We might not **know** we incurred it!
  - We might not know the **interest**!
  - Results of **poor practice**
    - See earlier testability examples!
- Intentional debt == deliberate, knowingly incurred
  - Needs an **identifiable rationale**
    - With a **scope**

*If you don't know the scope, it's probably not (fully) intentional*
Why Go Into Debt?

- 2.A **Short-Term** Debt
  - **Tactical** reasons
  - 2.A.1 "Big" Debt
    - **Significant** shortcuts
  - 2.A.2 "Little" (individual) Debt
    - **Tiny** shortcuts
- 2.B **Long-Term** Debt
  - **Strategic** reasons
Paying Down Debt

- Debt can become **unmanageable**
  - Even **manageable** debt can be **costly**
- Paying down debt **costs**
  - Debt **shifts** costs to the **future**
    - (But might **add** some costs now)
- **Refactoring** is the usual approach
  - But also things like **adding tests**

*Do you always have to pay down your debt?*
Good Debt Vs. Bad Debt

- **Good** debt
  - Has a clear *benefit*
  - Is *worth* the cost
  - Is *manageable*
- **Bad** debt
  - Skewed *cost/benefit ratio*
  - Less or un-manageable
- Debt can "*spoil*
  - Too much *good* debt can become *bad*
Program Equivalence
Many Equivalences

• Source code equivalent
  ■ Character equivalent
  ■ AST equivalent
  ■ Non-comment/names AST equivalent
• Translation equivalent
  ■ E.g., after compilation
• All-behavior equivalent
• Bisimilar
• Functionally equivalent
In General

*Two programs are equivalent (in some way) if we cannot distinguish them (in that way)*

- That is, if we **replace** one with the other
  - we don't notice!
- We may only "not notice" because we weren't **looking**
  - E.g., at some quality
Functionally Equivalent

Two programs are functionally equivalent just in case they implement exactly the same functionality.

- Functionality is means "Input-Output" behaviour
  - Internal structure doesn't matter
    - Programming language, algorithm, etc.
  - There can be behaviour differences (e.g., performance!)
What Behaviour Is "Functionality"?

The **functionality** of a software system is the *required* behaviour

Not ideal, as non-functional behaviour may be required

The **functionality** of a software system is the behaviour that performs some user task

The functionality is a **subset** of all behaviour
Functionality Equivalent (Reprise)

Two programs are *functionally equivalent* just in case they implement exactly the *same functionality*.

The *functionality* of a program are those behaviours which performs a user task.

Functionality may be changing, unknown, or misunderstood.

The set of functionally equivalent programs *depends on the functionality parameter*. 
FizzBuzz Example

Compare a "normal" FizzBuzz solution with a golf version:

```python
# Typical (8 lines, 196 chars)
for i in range(1, 101):
    if i % 3 == 0 and i % 5 == 0:
        print('FizzBuzz')
    elif i % 3 == 0:
        print('Fizz')
    elif i % 5 == 0:
        print('Buzz')
    else:
        print(i)

# Golf version (wrapped for easier viewing).
# (0 lines, 81 characters)
print(''.join(['
'.join(['Fizz']*i%3==0+['Buzz']*i%5==0)
or str(i) for i in range(1,101))])
```
Functionally Equivalent

Given a set of *required functionalities* $F$, and *two systems*, $S_1$ & $S_2$, $S_1$ is *functionality equivalent* (with respect to $F$) to $S_2$ if $S_1$ and $S_2$ enact $F$.

So, if two programs are *behaviourly equivalent* then they are *functionally equivalent*.

What happens if $S_1$ and $S_2$ don't *quite* enact the same $F$?
"Sufficiently" Functionally Equivalent

Given a set of required functionalities $F$, and two systems, $S_1$ & $S_2$, which enact functionality sets $F_1$ & $F_2$ (respectively), where, $F_1 \neq F_2 \neq F$, $S_1$ is sufficiently functionally equivalent to $S_2$ wrt $F$ if $F_1$ and $F_2$ share "enough" of an overlap with $F$.

Obviously, "enough" is a parameter!
**wc Example!**

- GNU `wc` has more functionality (and user-notable behaviour) than `miniwc.py`
  - Or other `wcs`!
  - Different flag options, find longest line, etc.
wc Example!

- Some behaviour is user visible but not "functional" (or interesting)
  - `wc --help --version` vs. `wc --version --help`
    - Non-equivalent in GNU `wc`
    - Do we care to preserve this?!
wc Example!

- What about **spacing**?
  - GNU `wc` has complex variable spacing
  - `wc . py` has tabs
- Are these two sufficiently functionally equivalent?
Refactoring
What Is Refactoring

Refactoring is a transformation of code into sufficiently functionally equivalent code that has "better" internal properties.

"Martin Fowler defines as "a change made to the internal structure of the software to make it easier to understand and cheaper to modify without changing its observable behavior" (Fowler 1999)" — McConnell, 24.2

- "Sufficiently functionally equivalent"
  - User observable/desirable behaviour is preserved
  - Up to some point
Examples

- For example, a **monolithic script**
  - has **low** testability (only system tests!)
  - replace it with a **set of functions**
    - e.g., for arg handling, counting, and printing results
  - result: **easy to test** script
- For example, **hard coded** values
  - great for getting going (tech debt!)
  - **refactor** by making them **configurable**
    - easier to tweak or eventually **make a parameter**
  - result: more **flexibility**!
Code Smells

- Problem **signs** (select sample, McConnell 24.2)
  - Code is **duplicated**.
  - A routine is **too long**.
  - A loop is **too long or too deeply nested**.
  - A routine has a **poor name**.
  - **Comments** are used to explain difficult code.
  - A program contains code that **seems like it might be needed someday**.
Known Debt

- Code smells indicate (potentially) unknown debt
- But there's explicit, known debt
  - Hacks done for *time pressure*
  - *Incomplete transitions* from earlier designs
  - *Learning* code
  - Technology *workarounds*
  - Code for *discarded* features
  - *Overengineered* code
What Refactoring Is Not

- Code **creation**
  - Refactoring might **enable** or facilitate new functionality
  - But you shouldn't add **while** refactoring
- Bug **fixing**!
  - Again, may facilitate
  - Refactoring may **reveal** or "fix" bugs
- Performance **tuning**
  - See above
  - Clean code may be faster...or not!
- Design changes or rearchitecting
  - **Prescursor** activity!
Refactoring Preconditions

- Tests, tests, tests
  - Even when applying "automatic" refactoring
  - Remember, **no change in behavior**
    - Up to a point at least!
- For **simple refactoring**
  - Use a tool!
    - e.g., renaming a routine
- For **complex refactoring**
  - Have a **plan**!
    - And test!
